the pandemic and generate practice recommendations from assessing electronic-pain-annotation and pen-to-paper-annotation by producing a detailed usability framework.

**Materials and Methods** This study followed the PRISMA scoping review guidelines. Online databases were searched from January 2015 to February 2021 for studies evaluating pain diagram usability in adults with musculoskeletal pain. Study quality was assessed using STROBE. An evidence gap map, framework and infographic were constructed.

**Results** 22 observational studies, 1 systematic review and 1 app review were included; of which 9 were high quality, 13 medium and 1 low (App review not assessed). 9 studies reviewed pen-to-paper-annotation, 14 reviewed electronic-pain-annotation and 1 both. Pen-to-paper-annotation and electronic-pain-annotations were found to be highly reliable (ICC 0.81–0.998), valid, and successful communication tools. Both had a positive relationship with outcome measures assessing psychological comorbidities, such as the widespread pain index. Gender specific electronic-pain-annotations enable better identification with the diagram and enhance communication about pain. Barriers involved lack of technology, interpretation, age, and pain experience. Automated weekly reminders were a completion facilitator. There were no studies directly comparing electronic-pain-annotation to pen-to-paper-annotation.

**Conclusion** Electronic-pain-annotation and pen-to-paper-annotation were both effective at communicating pain with electronic-pain-annotation allowing for more accurate quantification of pain extent. Gender specific electronic-pain-annotation allowed for better reporting of pain. Gaps included responsiveness in both modes and usability in electronic-pain-annotations which needs to be addressed to optimise integration into electronic health records.

**108 PROTECTIVE EQUIPMENT IN YOUTH ICE HOCKEY: ARE MOUTHGUARDS AND HELMET AGE RELEVANT IN EVALUATING CONCUSSION RISK?**

1,2Ash T Kolstad, 1,2,3Paul H Eliason, 1,2,3Jean-Michel Galameau, 1,2,3,4Amanda M Black, 1,2,3,4,5Brent E Hagel, 1,2,4,5,6,7Carolyn Emery, 7Sport Injury Prevention Research Centre, Faculty of Kinesiology, University of Calgary, 2500 University Drive NW, Canada; 2Integrated Concussion Research Program, University of Calgary, 2500 University Drive NW, Canada; 3Alberta Children’s Hospital Research Institute, University of Calgary, 28 Ohk Dr NW, Canada; 4Hotchkiss Brain Institute, University of Calgary, 2500 University Drive NW, Canada; 5O’Brien Institute for Public Health, University of Calgary, 2500 University Drive NW, Canada; 6Alberta Children’s Hospital Research Institute, University of Calgary, 28 Ohk Dr NW, Canada; 7Community Health Sciences, Cumming School of Medicine, University of Calgary, Canada

**Introduction** The high concussion burden in youth ice hockey is concerning. An important yet understudied area for prevention is protective equipment (e.g., wearing a mouthguard, age of helmet). Therefore, the objective of this study was to compare incidence rates of concussion between players based on mouthguard use and helmet age.

**Materials and Methods** This prospective cohort collected concussion information and player participation over five seasons (2013/14–2017/18) in male and female youth ice hockey players (ages 11–18). Baseline assessments were completed near the season start and collected reports on mouthguard use (yes, no), helmet age (newer/<2 years old, older/≥2 years old), and other important covariates (i.e., weight, age group, position of play, concussion history, body checking). Moreover, each player’s participation hours and the number of therapist-suspected and physician-diagnosed concussions were collected throughout each season. A multilevel negative binomial regression model was used to estimate the concussion incidence rate and incidence rate ratio (IRR) for equipment.

**Results** The model included 426 player concussions (suffered by 369 players) with 271,148.7 player-hours and was adjusted for covariates, clustered by team, and offset by player-hours. Results showed that players who reported wearing a mouthguard had a 28% lower concussion rate compared with non-wearers (IRR=0.72, 95%CI: 0.55–0.93) while no differences in the concussion rate between newer and older helmet ages (IRR=0.94, 95%CI: 0.76–1.16) were detected.

**Conclusions** Wearing a mouthguard was associated with significantly lower concussion rates; thus, policy mandating use should be considered in youth ice hockey. More specific helmet age categories may require further investigation.

**114 PREDICTORS OF RESPONSE TO NEUROMUSCULAR TRAINING WARM-UP PROGRAMS AMONG YOUTH**

1,2Anu Räsänen, 1,2Jean-Michel Galameau, 2Carla van den Berg, 2Lauren Benson, 2,3Oluwatoyosi Owoeye, 2,5,6,7Kati Pasanen, 2Paul Eliason, 3Brent Hagel, 5,6,7Carolyn Emery, 7Department of Physical Therapy Education – Oregon, College of Health Sciences – Northwest, Western University of Health Sciences, USA; 3Sport Injury Prevention Research Centre, University of Calgary, Canada; 4Hotchkiss Brain Institute, University of Calgary, Canada; 5Tonal Strength Institute, Tonal, USA; 6Department of Physical Therapy and Athletic Training, Doisy College of Health Sciences, Saint Louis University, USA; 7McCaig Bone and Joint Institute, Cumming School of Medicine, University of Calgary, Canada; 8Alberta Children’s Hospital Research Institute, University of Calgary, Canada; 9Tampere Research Center of Sports Medicine, UKK Institute for Health Promotion Research, Finland; 10Department of Pediatrics and Community Health Sciences, Cumming School of Medicine, University of Calgary, Canada

**Introduction** Neuromuscular training (NMT) warm-ups are effective in reducing injury risk in youth. Factors predicting the response to NMT in reducing injury risk are unknown, making this the objective of the present study.

**Materials and Methods** This is a secondary analysis of the intervention groups of randomized controlled trials evaluating NMT warm-ups among youth (11–18 years) [basketball (n=494), soccer (n=380), physical education (PE; n=919)]. Response was predicted based on age, sex, height, weight, sport/PE, one-year injury history, adherence (weekly sessions) to NMT, and balance ability (timed single-leg on balance pad). Generalized estimating equation analysis was used to estimate odds ratios (OR) with clustering on team/class, exchangeable correlation structure, robust variance estimator, and offset for exposure hours.

**Results** Adjusting for age, balance, injury history, sex and sport/PE, balance ability reduced the odds of injury [OR=0.955, (95%CI: 0.912–0.999)]. Predictors of non-response include previous injury [OR=1.895, (95%CI: 1.335–2.691)], female sex [OR=1.595, (95%CI: 1.119–2.274)], and playing basketball [OR=3.151, (95%CI: 1.616–6.142)]. Stratifying by sex, weekly NMT sessions did not predict injury in females, however injury history [OR=2.148, (95%CI: 1.394–3.311)] and basketball [OR=3.677, (95%CI: 1.538–8.679)] were associated with increased odds. Stratifying by sex and sport, female soccer players had lower odds associated with...
