Introduction Treatment of knee osteoarthritis with stem cells from microfragmented adipose tissue (AT) has shown promising results. Cryopreservation and biobanking of stem cells are important for research, treatment of aged patients, and for repetitive treatments. Our aim was, therefore, to investigate if viable stem cells could be isolated and expanded from cryopreserved microfragmented AT by two different isolation methods.

Materials and Methods Microfragmented abdominal AT from knee osteoarthritis patients was cryopreserved at -80°C in cryo-protectant-medium containing 10% dimethyl sulfoxide. The samples were thawed for stem cell isolation by tissue explant culture (TEC) and enzymatic digestion (ED), respectively. Viability, population doublings, and doubling time were assessed by trypan blue staining. Cell type was investigated using flow cytometry. Osteogenic and adipogenic differentiation was assessed quantitatively by Alizarin-Red-S and Oil-Red-O staining, respectively. Statistical analysis was performed using paired t-tests. p-values <0.05 were considered statistically significant.

Results Microfragmented AT from 7 patients was cryopreserved for a period of 46–150 days (mean (SD) 115.9 days (44.3 days)). Viable stem cells were successfully recovered and expanded from all patients using both isolation methods with no significant difference in viable population doublings or doubling time from passage 1 to 3 (p>0.05). Stemness was verified by surface markers and osteogenic and adipogenic differentiation. More pericytes were present when using TEC (25% (24%)) compared to ED (2% (2%)) at passage 4 (p=0.04).

Conclusion Viable stem cells can be isolated and expanded from cryopreserved microfragmented AT using both TEC and ED. TEC provides more clinically relevant pericytes than ED.

CONCUSSION INCIDENCE AMONGST YOUTH HANDBALL PLAYERS PARTICIPATING IN THE HEALTH AND PERFORMANCE PROMOTION IN YOUTH SPORT (HAPPY) RANDOMIZED CONTROLLED TRIAL

Lisbeth Lund Pedersen*, Morten Bjerg, Søren Carstensen, Jan Hartvigsen, Merete Møller. University of Southern Denmark, The Faculty of Health Sciences, Department of Sports Science and Clinical Biomechanics, Campusvej 55, Denmark

10.1136/bmjsem-2023-sportskongres2023.25

Introduction Knowledge of concussion in handball is limited. The aim of this study is to determine the incidence of concussion in Danish youth community handball.

Materials and Methods 758 players aged 11–17 years were followed prospectively as a part of a randomized controlled trial. Handball playing hours and head traumas were monitored weekly by the Oslo Sport Trauma Research Center Health questionnaire (OSTRC-H2) and a concussion specific question over 21 weeks using the app Athlete Monitoring. Players reporting a head injury via the OSTRC-H2 questionnaire or answered yes to the concussion specific question underwent a standardized 5–10-Minute telephone interview within 1 week.

Cases of concussion was defined according to the Consensus in Sport Group. Handball playing hours was defined as time spend in handball training and match. Incidence is reported as cases per 1000 playing hours.

Results 44 cases of concussion were identified. Overall incidence of concussion was 0.94 per 1000 hours [95% CI, 0.68–1.26]. Female athletes sustained twice as many concussions than male athletes (incidence rate ratio (IRR) 2.20 [95% CI; 1.09–4.84]). Concussion happened 9 times more often during match compared to training (9.09 [95% CI; 4.72–18.25]). No statistically significant difference in IRR between age groups (U13/U15 vs. U17; IRR 1.48 [95% CI; 0.59–3.24]) was found.

Conclusion This is the first study reporting concussion incidence in youth handball. Incidence was higher amongst female handball players compared to males and in match versus training. No difference in concussion incidence was found between age groups.

DOES AN ACTIVITY MODIFICATION STRATEGY FOR ADOLESCENTS WITH PATELLOFEMORAL PAIN AND OSGOOD-SCHLATTER AFFECT SEDENTARY TIME? AN ANCILLARY ANALYSIS

Magnus Bye Blumenfeld*, 1/2,3,4 Sinead Holden, 1/2,3,4,5 Kristian Thorborg, 1/2,3,4,5 Michael Skovdal Rathleff. 1/2,3 Center for General Practice, Department of Clinical Medicine, Aalborg University, Fyrkildevej 7, Denmark; 3,4 Department of Health Science and Technology, Faculty of Medicine, Aalborg University, Fyrkildevej 7, Denmark; 5 School of Medicine, University College Dublin, Dublin 4, Ireland

10.1136/bmjsem-2023-sportskongres2023.26

Introduction Two clinical trials tested a new management strategy for adolescents with Patellofemoral Pain (PFP) and Osgood-Schlatter Disease (OSD). The strategy consisted of activity modification (a 4-week break from sport followed by progressive return to sport), education, and exercises. This strategy appeared to improve self-reported symptoms and detrimental effects on adolescents’ sedentary behavior. The aim of this study was to investigate the changes in sedentary behavior during an activity modification management strategy for PFP and OSD.

Materials and Methods This ancillary analysis included data from two single arm trials of activity modification, education, and exercises of 177 adolescents’ with PFP or OSD. ActiGraph GT3X+ measured physical activity and sedentary time before and during the trial (at four weeks follow-up)
when adolescents were instructed to modify sports participation. Data was only included if they had a valid week which consisted of at least 4 days with 10 hours of wear-time. Time spent in consecutive sedentary bouts of ≥10 minutes was used to calculate the average daily sedentary time.

Results Baseline sedentary time for adolescents with PFP and OSD were 344 (±74) and 349 (±39) min/day, respectively. For adolescents with PFP the mean change in sedentary time was 14 min/day (95% CI, -3 to 30 min) and 8 min/day (95% CI, -7 to 24) for OSD during activity modification.

Conclusion A management strategy focusing on activity modification, education, and exercises was associated with none or only small changes in sedentary time.

GOOD SHORT-TERM EFFECT OF SELF-MANAGEMENT REHABILITATION IS ASSOCIATED WITH LONG-TERM SUCCESSFUL OUTCOME IN ADOLESCENTS WITH PATELLOFEMORAL PAIN AND OSGOOD-SCHLATTER

1,2,3Michael Skovdal Rathleff*, 1Kilian Thorborg, 2Alessandro Andreucci, 1Henrik Riel, 1Department of Health Science and Technology, Aalborg University, Denmark; 2Center for General Practice at Aalborg University, Aalborg University, Denmark; 3Sports Orthopaedic Research Center – Copenhagen (SORC-C), Department of Orthopaedic Surgery, Aarhus University Hospital, Institute for Clinical Medicine, Copenhagen University, Denmark

Introduction Short-term self-reported changes may be more strongly associated with long-term prognosis as they describe a disease trajectory and not a state. This study aimed to investigate the association between Global Rating of Change (GROC) after 4 weeks and the outcome after 12 months among adolescents with non-traumatic knee pain (Patellofemoral Pain (PFP) or Osgood-Schlatter (OSD)).

Material and Methods We included data from two prospective clinical trials including adolescents (aged 10–14 years) with PFP (N=151) or OSD (N=51) who underwent a self-management rehabilitation programme including education and exercise. Primary outcome was a 7-point GROC ranging from “much improved” to “much worse”. Adolescents were considered to have a successful outcome if they reported being “much improved” or “improved”. Outcomes were collected after 4 weeks and 12 months.

Results Among adolescents with an unsuccessful outcome after 4 weeks (58% of all adolescents), 78% had a successful outcome after 12 months. Among those with a successful outcome after 4 weeks (42% of all adolescents), 94% had a successful outcome after 12 months. Having a successful outcome after 4 weeks increased the relative risk of a successful outcome after 12 months (relative risk 1.21 [95%CI: 1.07–1.38] and absolute risk difference: 16%).

Conclusion Self-reported improvement after 4-weeks of treatment is associated with better outcomes after 12 months. Importantly, despite no improvement after 4 weeks, a large proportion of adolescents between 10 and 14 years of age will report improvement after 12 months. This highlights the importance of following the rehabilitation programme irrespective of short-term improvements.

10-YEAR PROGNOSIS OF ADOLESCENT KNEE PAIN – A PROSPECTIVE POPULATION-BASED COHORT STUDY

1,2,3Michael Skovdal Rathleff*, 1,2Pernille Brandum, 1Eva Roos, 1Jane Bay Sørensen, 1Jesper Bie Larsen, 1Jens Lykkegaard Olesen, 1,5Alison Chang, 1,5Sewad Holden. 1Department of Health Science and Technology, Aalborg University, Denmark; 2Department of Occupational Therapy and Physiotherapy, Department of Clinical Medicine, Aalborg University Hospital, Denmark; 3Center for General Practice at Aalborg University, Denmark; 4Center for Muscle and Joint Health, Department of Sports and Clinical Biomechanics, University of Southern Denmark, Denmark; 5Department of Physical Therapy and Human Movement Sciences, Northwestern University Feinberg School of Medicine, USA; 6UCD Clinical Research Centre, School of Medicine, University College Dublin, Dublin, Ireland

Introduction Knee pain affects one in three adolescents. No studies have prospectively evaluated the long-term impact of knee pain in later life. The Adolescent Pain in Aalborg (APA
